

CAV Model Conceptualisation and Feasibility Study

Executive summary:

The development of Connected Automated Vehicles (CAV) requires integrated systems to maintain continuous connection to external domains as to allow for intercommunication between other road going vehicles. While communicating, CAV may be vulnerable to potential network-based threats from external sources. The following report attempts to provide a surface level configuration and costing for a testing platform to challenge the resilience of CAV onboard processes from externally based attacks. Modern methods of autonomous navigation and control require input from a multiple integrated systems. The components listed below are commercially available and reflect current technology within CAV control and communication. These systems will be utilised to determine their robustness to potential incidents.

The test assembly contains integrated circuits which utilise multiple forms of sensory data acquisition. Research conducted into industry wide applications of CAV has shown that the primary means of sensory input is centred around LiDAR, stereo camera-based computer vision, and ultrasonic perception. The integration of these systems enables CAV to interpret their surrounds based upon these sensory devices which render a 3D map of the vehicles environment. Multi-channel sensing is vital within CAV as their ability to navigate their environment is based upon the accuracy and availability of information. Multi-channel sensing enables the CAV to verify and adjust its sense of state based upon the collective information channels, rather than from a singular source. This creates more robust spatial awareness within the CAV and enables a variety of sources to be utilised to confirm its state with respect to environmental conditions.

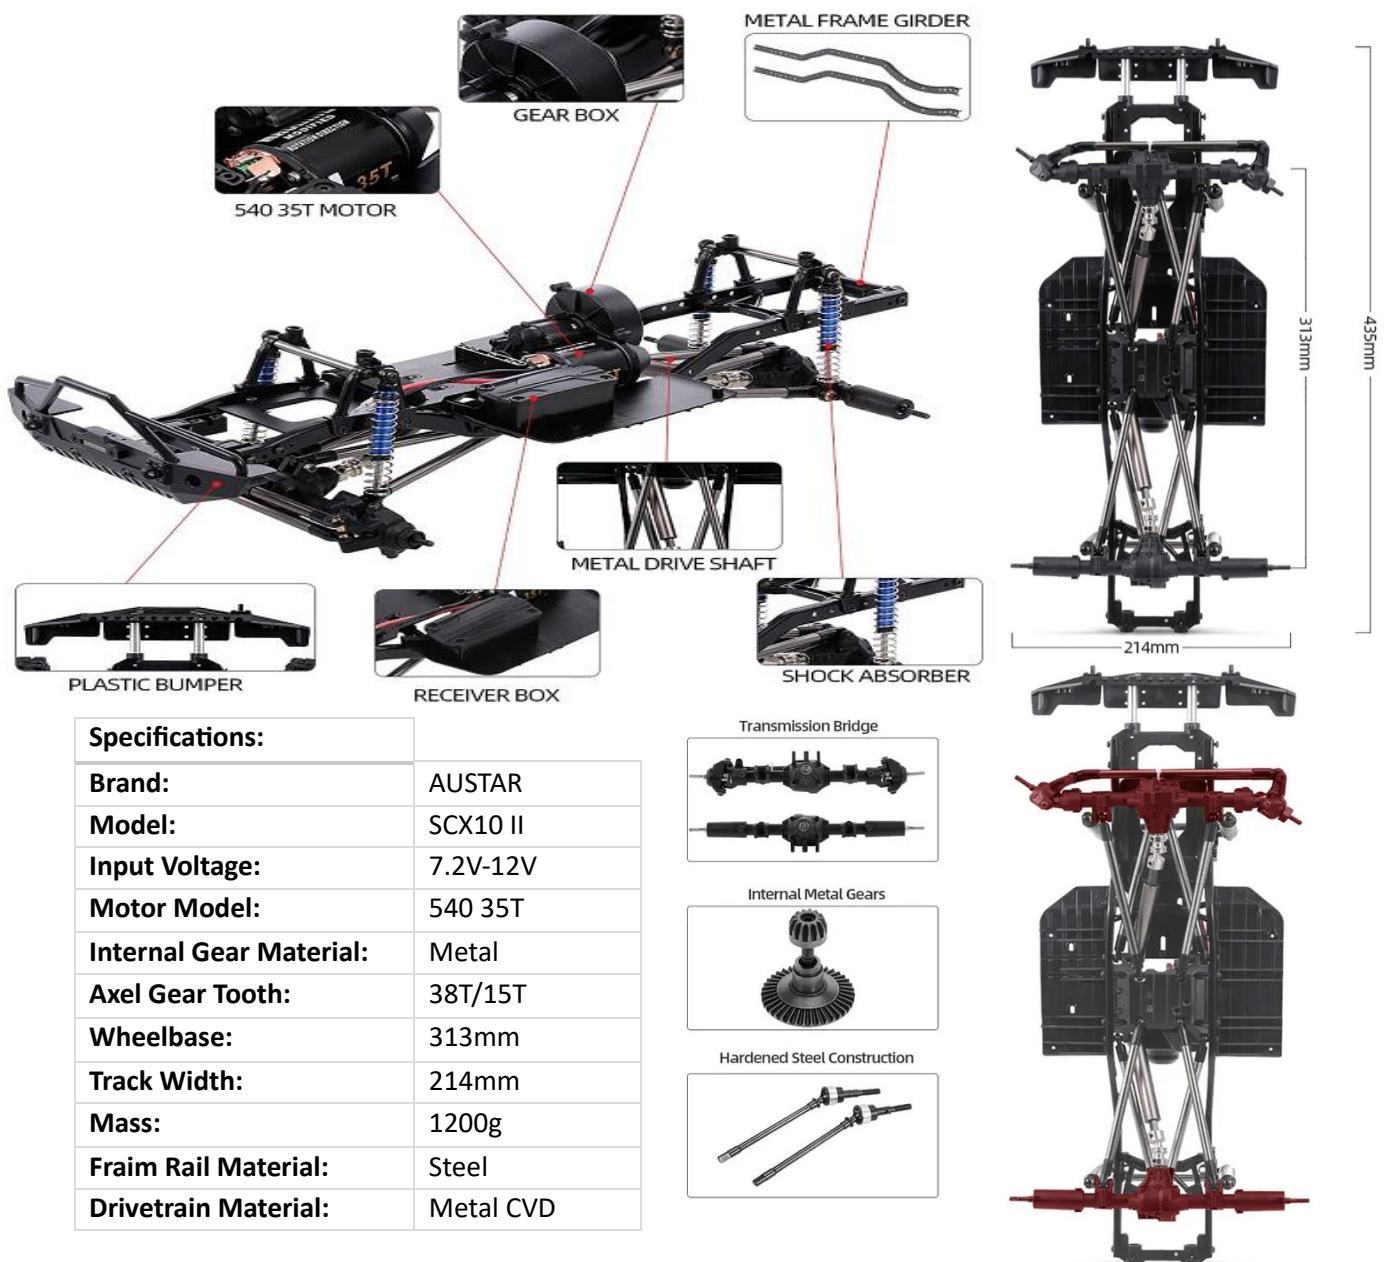

Communications has been considered as a primary attribute within the model. The means of communication will encompass a range of transceivers consisting of WIFI, 5G, Bluetooth, GPS and radio frequency modules. The CAV has onboard processing capabilities which allow the vehicle to determine its spatial awareness and navigate autonomously through its environment. The information concerning the state of the vehicle can then be transmitted to a third party where it's current state can be interpreted and modified as required. The secure connection between the vehicle and the third party is the primary focus of this study.

The control of the CAV will be determined through the onboard computer, where localised and external information will render a map of its immediate surroundings and will pass on navigational information to an onboard Micro-Controller Unit (MCU). The MCU will be dedicated to the control of the vehicles motion, reception of localised data and receiving instructions from the on-board computer.
